In general, a solution to the total separation problem can be separated into two parts: The adsorbent in the column may be any of a variety of materials. Adsorption. 5- Microporous cellulose adsorbents and activated alumina are two of the most popular types of commercially available adsorbents. Their pore sizes range from about 5 Angstroms to about 100 Angstroms. Although adsorption does work, it does not work perfectly. In addition, the use of adsorbents is not without problems. However, there is a host of adsorbents that are used commercially and will be discussed in this section. Manufacturing Process: The raw materials are fed into an extruder and the thermoplastics are melted into a polymeric

plastic such as polyethylene or polypropylene. The process for producing porous polymer particles is summarized below. First the polymer is melted in an extruder and forced through a venturi to form a uniform melt. Then the polymer is fed into a gas flow reactor. Air or nitrogen gas is blown through the melt to form finely divided gas bubbles which can be injected into the polymer melt. The gas expands in the melt causing the polymer to foam. The foamed polymer is then solidified and crushed into particles. This study evaluated the ability of a sonication method to produce porous polymer particles from standard polymeric materials. The polymers used in this study are polyethylene, polypropylene, and

polystyrene. Two blends were also examined: polyethylene and polypropylene and polystyrene and polypropylene.
